Fig. S1 Correlation between calculated and experimental $D_{H}$

Fig. S1. Correlation between calculated and experimental mRDCs ( $\mathrm{D}_{\mathrm{CH}}{ }^{\text {calc }}$ and $\left.\mathrm{D}_{\mathrm{CH}}{ }^{\text {exp }}\right)$ after different optimizations of the global 4 H structure. A) Model helices used and optimization with three parameters ( $\psi, \omega_{\mathrm{AD}}$ and $\omega_{\mathrm{BC}}$ ), corresponding to fit M(3) r1 in Table S1a. Filled blue: C1'-H1' of A- and D -helix; filled red/green: C1'-H1' of Band C-helix; red plus: $\mathrm{C} 3^{\prime}-\mathrm{H} 3^{\prime}$ of A and D-helix; blue plus: $\mathrm{C}^{\prime}-\mathrm{H} 4^{\prime}$ of A- and D-helix; red x: C3'-H3' of B- and C-helix; blue x: C4'-H4' of B- and C-helix. Note the offset of the H3'-C3' couplings of the A- and D-helix (red plus) from the diagonal (dotted line is through H3'-C3' of helix AD and indicates the correlation between experimental and calculated couplings). Similar correlated offsets can be seen for the H3'-C3' of the B-and Chelices and for the H 4 '- C 4 ' of the B - and C-helices. Table S 1 b gives the required additional group-wise $\omega$-rotation to obtain optimal correlation for these vectors. B) As in A except additional group-wise optimization of H3'-C3' and H4'-C4' vectors (fit M(10) r2 of Table S1a). C) Experimental helix used with three-parameter optimization (color coding as in A; fit E2(3)_b1 in Table S1a). D) Experimental helices are used and with additional group-wise optimization of H3'-C3' vectors (fit E2(11)_b2 in Table S1a; color coding as in A).

${ }^{a}$ First column contains the fit identifier (see below). The number of adjustable parameters is given between parentheses; when this number is 3 , the adjustable parameters are the three angles that define the conformation of the $4 \mathrm{H}\left(\psi, \omega_{\mathrm{AB}}\right.$ and $\omega_{\mathrm{CD}}$, see text). When the number is between 3 and 11 , in addition the H 3 '- C 3 ' dipolar vectors can adjust as a group in each of the helices A, B, C and D, and similarly for the groups of $\mathrm{H}^{\prime}$ '- $\mathrm{C}^{\prime}$ ' dipolar vectors (the final numbers are found in Table S1b). A number between 3 and 11 indicates that only a few of these extra parameters were used. When the number is between 11 and 15 , in addition the angles $\omega_{\mathrm{B}}$ and $\omega_{\mathrm{D}}$ and $\theta_{\mathrm{B}}$ and $\theta_{\mathrm{D}}$ were allowed to adjust. $\mathrm{M}(3) \_$r1: AB and CD helices with B-DNA geometry were used and the CTTG loop as derived by Ippel et al. (reference 14). The molecular $\chi$-tensor was calculated as the tensor sum of the base $\chi$ tensors using an average $\chi_{\mathrm{zz}}$ of $-1310^{-34} \mathrm{~m}^{3}$ (Table 1a); the fit results are shown in Figure 2 and coded as r1. $\mathrm{M}(10)_{\_} \mathrm{r} 2$ : as in $\mathrm{M}(3) \_\mathrm{r} 1$ except for the extra fitting parameters, r 2 is code for fit in Figure 2; $\mathrm{M}(12)$ : as in $\mathrm{M}(3) \mathrm{r}_{\mathrm{r}} 1$ but with 12 fitting parameters, see above. $\operatorname{Mbs}(3)$ : as in M3_rl except the fit was performed with base-specific values to calculate molecular $\chi$-tensor (see Table1); this was done to test the effect of base-specific values. $\operatorname{Mbs}(10) \_\mathrm{r} 3$ : as in $\mathrm{M}(10) \_$r2 but with base specific values to calculate molecular $\chi$-tensor (see Table 1 ), r3 is code of fit in Figure 2. $\mathrm{Mbmin}(10)$ : as in $\mathrm{M}(10)$ except $\chi_{z z}$ was increased to $-10.510^{-34} \mathrm{~m}^{3}$ (minus one standard deviation); this was done to test the effect of the uncertainty in $\chi_{z z}$ on the fit results. $\operatorname{Mbplus}(10)$ : as in $\mathrm{M}(10)$ except that $\chi_{z z}$ was set to $-15.510^{-34} \mathrm{~m}^{3}$ (plus one standard deviation). E1(3)_z1: fit with AD and BC helices taken as in an experimental structure which was based on classical constraints, such as NOEs and J-couplings (reference 3), zl code of fit in Figure 2. The structure used was close to the average of the 20 lowest energy structures. E1(5): as in E1(3) but with extra adjustment of H3'-C3' groups of dipolar vectors. E2(3)_b1: fit with AD and BC helices taken from experimental structure based on NOE and J-coupling data, b1 is the code for the fit in Figure 2. The structure chosen was closest to the average and had an inter-helix angle of ca. $-70^{\circ}$. E2(11)_b2: as in E2(3)_b1 but additional adjustable parameters (see above), b2 code for the fit in Figure 2; the main improvement stems from the removal of small kink between the D-helix and A-helix ( $\Delta \theta_{\mathrm{D}}=-8^{\circ}$ and $\Delta \theta_{\mathrm{A}}=2^{\circ}$ ).
${ }^{\mathrm{b}}$ Rmsd: root-mean-square deviation of the fit.
${ }^{\mathrm{c}} \mathrm{R}$ : linear correlation coefficient of the fit; Q: the Q-value of the fit, $Q=\sum_{i}\left(D_{C H, i, \text { alc }}-D_{C H, i, \text { exp }}\right)^{2} / \sum_{i}\left(D_{C H, i, \text { exp }}\right)^{2}$ (see reference 5 i$)$
${ }^{\mathrm{d}} \psi, \omega_{\mathrm{AD}}$, and $\omega_{\mathrm{BC}}$ optimal values (see text for definition). The number between parentheses is the rmsd of the distribution obtained via Monte Carlo simulation. For the Monte Carlo simulation a normal error distribution was used with a standard deviation of 0.5 Hz on the experimental $\mathrm{D}_{\mathrm{CH}}$ values; 100 samples were taken and for each the fit was carried out. The molecular reference axes frame is defined in the main text. To relate $\omega_{\mathrm{AD}}$ and $\omega_{\mathrm{BC}}$ to the molecular structure within this frame a reference vector in each helix needs to be defined. For this, the vector $\mathrm{v}_{\mathrm{ABCD}}$ is defined. It points from $\left\langle\mathrm{C} 1^{\prime}\right\rangle_{\mathrm{AD}}$ to $\left\langle\mathrm{C} 1^{\prime}\right\rangle_{\mathrm{BC}}$, the average C 1 ' positions of the four junction residues in the AD and $B C$ helix. Within the $A D$-helix, this vector is called $v_{A D}$ and within the $B C$-helix $v_{B C}$. The orientation of $v_{A B C D}$
in the $\mathrm{x}, \mathrm{y}$ plane is defined by the angle the vector makes with the x -axis of the reference. This angle is called $\omega_{\mathrm{ABCD}}$ and similarly, the angles $\omega_{\mathrm{AD}}$ and $\omega_{\mathrm{BC}}$ for $\mathrm{v}_{\mathrm{AD}}$ and $\mathrm{v}_{\mathrm{BC}}$. The search for the optimal fit between experimental and calculated RDC always starts from the parallel orientation of the helices. In this situation, the $\omega$ angles are called $\omega_{\text {refABCD }}$, and similarly for $\mathrm{v}_{\mathrm{AD}}$ and $\mathrm{v}_{\mathrm{BC}}, \omega_{\mathrm{refAD}}\left(=\omega_{\mathrm{refABCD}}\right)$ and $\omega_{\mathrm{refBC}}\left(=\omega_{\mathrm{refABCD}}\right)$. Subsequently, the $\omega$-rotations of the AD and BC helices are carried out, giving $\Delta \omega_{\mathrm{AD}}$ and $\Delta \omega_{\mathrm{BC}}$, respectively (the $\omega$-rotations of the AD and BC helices are around a point centered on the $\left\langle\mathrm{Cl}^{\prime}\right\rangle_{\mathrm{AD}}$ and $\left\langle\mathrm{Cl}{ }^{\prime}\right\rangle_{\mathrm{BC}}$ positions, respectively). These $\Delta \omega_{\mathrm{AD}}$ and $\Delta \omega_{\mathrm{BC}}$ rotations affect the $\mathrm{x}, \mathrm{y}$-plane orientation of $\mathrm{v}_{\mathrm{AD}}$ and $\mathrm{v}_{\mathrm{BC}}$. In the final optimal orientation, $\omega_{\mathrm{AD}}$ and $\omega_{\mathrm{BC}}$ are then given as $\Delta \omega_{A D}+\omega_{\text {refAD }}\left(=\Delta \omega_{A D}+\omega_{\text {refABCD }}\right)$ and $\Delta \omega_{B C}+\omega_{\text {refBC }}\left(=\Delta \omega_{B C}+\omega_{\text {refABCD }}\right)$, respectively. Hence, $\omega_{A D}$ and $\omega_{\mathrm{BC}}$ are the angles off the x -axis of the molecular reference axes frame of the projection of $\mathrm{v}_{\mathrm{AD}}$ and $\mathrm{v}_{\mathrm{BC}}$ on the $\mathrm{x}, \mathrm{y}$ plane in the final optimal orientation. For the 4 H with model B-DNA helices $\omega_{\text {refABCD }}=-170^{\circ}$. For the mRDCoptimized 4 H with helices from experimental NOE-based 4 H structures: $\omega_{\mathrm{refABCD}}=-161^{\circ}(\mathrm{E} 1) ; \omega_{\mathrm{refABCD}}=-140^{\circ}$ (E2).
${ }^{\mathrm{e}} \chi_{\mathrm{ax}}$ ' and R of the optimized 4 H . R is defined in the main text and $\chi_{\mathrm{ax}}$, equals $\mathrm{D}_{\mathrm{CH}}{ }^{\text {max }}$ and is expressed in Hz .
The Euler angles defining the orientation of the molecular $\chi$-tensor in the final optimal conformation and with respect to the defined reference axes system (see main text).
${ }^{\mathrm{g}}$ The average Rmsd obtained from the Monte Carlo simulation; generally the Monte Carlo Rmsd's tend to spread in such a way that they are somewhat lower on average also for the other fits.
${ }^{\text {h }}$ The additional $\omega$-rotation of the group H3'-C3' vectors and the group of H4'-C4' vectors are given in Table S1b.
${ }^{i}$ The fit has in addition separate $\omega$-rotation of D- and C-helices. The numbers given are $\omega_{\mathrm{A}}$ and $\omega_{\mathrm{B}}$ for the A- and B-helices, respectively, the corresponding $\omega_{\mathrm{D}}$ and $\omega_{\mathrm{C}}$ are behind slash.
${ }^{\mathrm{j}}$ The fit has in addition separate $\omega$-rotation of helix D ( $\omega_{\mathrm{D}}$ behind slash).

[^2]
[^0]:    ${ }^{\mathrm{a}} \Delta \omega$, the additional rotation of the vector compared to the starting structure;
    ${ }^{\mathrm{b}} 3$ ' A stand for the group of H3'-C3' vectors in helix A etc.

[^1]:    ${ }^{\text {a }} 8$ - 35 indicate the vector going C 1 ' of residue 8 to C 1 ' of residue 35 etc.;
    ${ }^{\mathrm{b}}$ Model indicates the C1' vectors orientations in the starting model with B-DNA helices, while E1(0) and E2(0) indicate the experimental NOE-based structures.

[^2]:    ${ }^{\text {a }}$ The $\mathrm{J}_{\mathrm{CH}}$ were measured at four different fields as described via the method of reference $8 .{ }^{\mathrm{b}} \mathrm{Rmsd}$ of each measured J-coupling. ${ }^{\mathrm{C}}$ Jo: the J -coupling at Bo is zero as derived from the least-squares fit $\mathrm{J}_{\mathrm{CH}}=$ slope $\mathrm{Bo}^{2}+\mathrm{Jo}$. ${ }^{\mathrm{d}} \mathrm{D}_{\mathrm{CH}}=$ slope $*(64.02-15.9616)$ and Rmsd is standard deviation in $\mathrm{D}_{\mathrm{CH}}$.
